## Goal

The purpose of this study was to assess the quantitative performance and advantages of PAHs and PCBs using the Thermo Scientific ${ }^{\text {Tm }}$ Orbitrap Exploris ${ }^{\text {Tm }} \mathrm{GC}$ in addition to screening of unknown soil contaminants.

## Introduction

Polychlorinated biphenyls (PCBs) and polyaromatic hydrocarbons (PAHs) are toxic organic compounds that can contaminate soils, air, sediments, and water as a result of natural and anthropogenic processes. PCBs and PAHs are resistant to environmental degradation and can be transported over long distances. Moreover, due to their lipophilicity these chemicals can undergo biomagnification and accumulation in the food chain and can pose significant health risks to humans. Their toxicity even at very low concentrations means that their presence in the environment needs to be monitored so that the risk of uptake of these compounds into to the food chain and subsequently into human populations is minimized.

More recently it has become apparent that oxidized and substituted derivatives of PAHs (such as oxy and methyl PAHs) have similar or increased toxicities compared to nonsubstituted versions; therefore, governments have already began monitoring them in soil and particulate matter., ${ }^{12}$ Nitrogen, sulfur, and oxygen-containing polyaromatic heterocycles (NSO-PAHs) are another class of compounds that have gained interest due to their ubiquitous presence in the environment and lack of data on their toxicities. ${ }^{2,3}$

PCBs and PAHs (and derivatives) are typically analyzed by gas chromatography (GC) coupled to mass spectrometry (MS). The challenges for the analysis of PAHs and PCBs are the requirement for complicated and costly sample preparation such as Sohxlet extraction. Often long chromatographic separations (>40 min per sample) are required, which overall will result in low sample throughput and high cost of analysis.

To comprehensively characterize an environmental sample, multiple methods are employed for both the sample preparation and GC-MS analysis of these compounds. Having multiple chromatographic methods for the same sample increases the requirement for both labor and instrumentation. Multiple methods and chemists to review the process and report the data add to the time and cost of analysis.

In this application note a consolidated approach for the rapid and cost-effective analysis of sixteen EPA PAHs, seven marker PCBs, three oxyPAHs, ten methylPAHs, and nine NSO-PAHs in soil samples using a sensitive HRMS instrument was employed. For this, a modified QuEChERS sample extraction and clean up was investigated. Chromatographic separation of target compounds was optimized for a <20 min/sample method and detection was achieved using the Orbitrap Exploris GC system.

The evaluation of system robustness and method suitability for PAH and PCB GC-MS analysis was outside of the scope of this application but is discussed in a supporting technical note (TN10728).

## Experimental

## Sample preparation

Calibration standards containing 45 native PCB, PAHs, methyl PAHs, oxyPAHs, PANHs, PASHs, and PAOHs at twelve concentration levels (Appendix 1 - Table 1), and 14 ( ${ }^{13} \mathrm{C}$-labeled) internal standards (Appendix 2 - Table 2), were acquired from Fisher Scientific, AccuStandards, and Wellington Laboratories Inc. (Ontario, Canada).

For the calculation of MDLs and LOQs QuEChERS soil extract was spiked at $0.5,1.0,1.5,2.5$, and $5.0 \mathrm{pg} / \mathrm{\mu L}$. Soil was freeze dried, homogenized, and sieved prior to a modified QuEChERS extraction and clean up procedure. A summary of the QuEChERS methodology can be seen in a recent application note (AN10720).

## GC-MS analysis

An Orbitrap Exploris GC instrument equipped with the ExtractaBrite ${ }^{\text {TM }}$ electron ionization source was used for this analysis. This configuration allows vent-free column changes and ionization source maintenance in under 2 minutes representing a 98\% time saving versus traditional venting approaches, which take up to 4 hours. This is achieved using state of the art NeverVent technology, which increases laboratory productivity through the minimization of instrument downtime.

Liquid injections of the sample extracts were performed using a Thermo Scientific ${ }^{\text {Tm }}$ TriPlus ${ }^{\text {Tm }}$ RSH series autosampler and chromatographic separation was achieved by a Thermo Scientific ${ }^{\text {r"m }}$ TraceGOLD ${ }^{\text {mw }}$ TG-5 SilMS $30 \mathrm{~m} \times$ 0.25 mm i.d. $\times 0.25 \mu \mathrm{~m}$ film (P/N 26096-1420) capillary column. Additional details of instrument parameters are displayed in Tables 1 and 2. Full details of all consumables used can be found in the Thermo Scientific ${ }^{T w}$ AppsLab ${ }^{T \times 1}$ library.

## Data processing

Data were acquired using full scan (FS) mode, processed, and reported using Thermo Scientific ${ }^{\text {TM }}$ Chromeleon ${ }^{\text {TM }} 7.3$ chromatography data system (CDS). Additional screening of unknowns was performed using Compound Discover software. Thermo Scientific ${ }^{\text {TM }}$ Compound Discoverer ${ }^{\text {TM }}$ software, version 3.2, was also used for spectral deconvolution, NIST library searching, and compound identification using the El and Cl nodes.

## Results and discussion

Chromatography, selectivity, and linearity were evaluated using solvent based standards. Assessment of sensitivity (as matrix detection limits and limits of quantitation), recovery, and selectivity were performed in soil using a modified QuEChERS extraction method, which is described in the experimental section.

## Chromatography

All compounds were analyzed in <20 min and excellent separation of the critical pairs was obtained for the 16 EPA PAH standard (i) phenanthrene/anthracene, (ii) benzo(a) anthracene/chrysene, (iii) benzo(b)fluoranthene/benzo(k) fluoranthene (Figure 1, A-D). As expected, with fast multiresidue methods of this nature, some coelution did occur in which case the data was reported as a sum of the combined area (ex: included (i) 1-ethylnapthanalene/ 2-ethylnapthalene, (ii) 1,3-dimethylnapthalene/ 1,6-dimethylnapthalene). Due to the superior inertness of the TraceGOLD silphenylene GC columns, excellent peak shape was observed for all compounds including the strongly basic compound quinoline which had a European Pharmacopeia (EP) asymmetry value of $1.0^{3}$.

Due to the diversity of sample matrices with various degrees of complexity, selectivity can be challenging in GC-MS analysis of soils. An example of sample complexity is shown in Figure 1, E-F as an overlay of the TIC El full
scan of a sonicated unspiked QuEChERS soil extract (top chromatogram) and of a FS XIC (bottom chromatogram) showing the incurred residues.

Figure 1. Example chromatograms showing overlaid native PAHs and PCBs FS XICs for a $50 \mathrm{pg} / \mu \mathrm{L}$ ( 50 pg on column (OC)) solvent standard in $n$-hexane with excellent chromatographic peak shapes for all compounds in $<20 \mathrm{~min}$. A) Peak shape for nitrogen containing polyaromatic heterocycle quinoline with peak asymmetry of 1.0; (B) Resolution of critical components phenanthrene and anthracene with EP resolution of 1.5; (C) Resolution of critical components benzo(a)anthracene and chrysene with chromatographic resolution of 1.3; (D) Resolution of critical components benzo(b)fluoranthene and benzo(k)fluoranthene with EP resolution of 1.0. (E) QuEChERS soil extract unspiked, FS, m/z=50-550; (F) QuEChERS soil extract unspiked, native incurred residue XICs; Compounds: 1= Quinoline, 2=Fluorene, 3=Dibenzothiophene, 4, 5=Phenanthrene/Anthracene $6=$ Fluoranthene, $7=$ Pyrene, 8, $9=$ Benzo[a]anthracene,Chrysene, 10=5,12-Napthacenequinone, 11, 12=Benzo[b/k]fluoranthene, 13=Benzo[a]pyrene, $14=$ Indeno[1,2,3-cd]pyrene, 15=Dibenzo[a,h]anthracene, 16=Benzo[ghi]perylene. $\mathrm{C}^{13}$-labeled internal standards were not displayed to show native peak shapes clearly.

## Sensitivity: determination of method detection limits (MDLs)

To practically assess the MDLs, $\mathrm{n}=18$ replicate injections of the lowest serially diluted matrix-matched standard ( $0.5,1.0,2.5 \mathrm{pg} / \mathrm{uL}$ ) with a peak area $\%$ RSD of $<15 \%$ were used. The MDL was then calculated by considering the injected amount, peak area \% RSD, and t-score of 2.567, corresponding to 17 ( $n-1$ ) degrees of freedom at the $99 \%$ confidence interval (Figure 2). The MDL values calculated ranged from 118 to 475 fg on column (corresponding to $0.1-0.5 \mu \mathrm{~g} / \mathrm{kg}$ in sample).

Sensitivity: determination of limit of quantitation (LOQ) Method LOQs were calculated using serially diluted matrixmatched standards at $0.5,1.0,2.5$, and $5.0 \mathrm{pg} / \mu \mathrm{L}$. Eighteen ( $\mathrm{n}=18$ ) replicate injections of each of the diluted standards ranging between $0.5 \mathrm{pg} / \mu \mathrm{L}$ and $5.0 \mathrm{pg} / \mu \mathrm{L}$ were performed ( $0.5-5.0 \mu \mathrm{~g} / \mathrm{kg}$ in sample) (Appendix 3 - Table 3).

The criteria used to assess individual LOQs were:

- Ion ratios within $\pm 30 \%$ of the expected values calculated as an average across a calibration curve ranging from 0.1 to $500 \mathrm{pg} / \mu \mathrm{L}$ (corresponding to $0.1-500 \mu \mathrm{~g} / \mathrm{kg}$ in sample, Figure 3)
- Peak area repeatability of < $15 \%$ RSD

Figure 2. Graph showing individual MDLs (as detectable fg on column) for 45 native PCB, PAH, methyl PAH, oxyPAH, and NSO-PAHs calculated from $\mathrm{n}=18$ replicate injections of the lowest serially diluted matrix-matched standards. *1,8-Dimethyl naphthalene 1.0 pg OC had a peak area \% RSD $>15 \%$ so the nearest standard 2.5 pg OC was used giving a higher MDL; however, by using a lower amount OC $\sim 1.5 \mathrm{pg}$ the true MDL value would be expected to be lower.

Figure 3. Graphs showing ion ratio consistency for selected PAHs and PCBs. (A) Naphthalene; (B) PCB 118, over n=18 replicate injections at the LOQ level. The average ion ratio \% deviation calculated from the calibration range is displayed as a green dotted line in the center. The $\pm 30 \%$ upper and lower ion ratio tolerance windows are also defined, and for all PAHs and PCBs the ion ratio \% deviation for injections were within specification. This also illustrates how using Chromeleon CDS interactive charts allows the user to easily handle and interpret MS data.

## Linearity

Linearity was determined using solvent standards at concentrations $0.1-500 \mathrm{pg} / \mu \mathrm{L}$. The calibration of each compound was performed using the linear/average calibration factor function in Chromeleon CDS (AvCF) over three injections at each concentration level (Figure 4).

All compounds show excellent linear responses with coefficients of determination $R^{2} \geq 0.995$, and average calibration factors \%RSD across the calibration range being $<13 \%$. The R ${ }^{2}$ values ranged from 0.9951 to 1.0000 with an average value of 0.999. (Appendix 4 - Table 4).

Figure 4. (A) Linearity of example PAHs and PCBs as demonstrated using solvent-based calibration curves ranging from 0.1 to $500 \mathrm{pg} / \mu \mathrm{L}$ (corresponding to $0.1-500 \mu \mathrm{~g} / \mathrm{kg}$ in sample). Average calibration factor function (AvCF) was used in Chromeleon CDS and three replicate injections at each concentration with internal standard adjustment were performed. Coefficient of determination $\left(R^{2}\right)$ and average calibration factor values (AvCF \%RSD) are displayed. (B) A magnified region of the calibration for PCB 180 ranging from 0.4 to $10 \mathrm{pg} / \mu \mathrm{L}$ is shown (corresponding to $0.4-500 \mu \mathrm{~g} / \mathrm{kg}$ in sample) showing excellent precision and accuracy for triplicate injections per point.

## Recoveries

Seven replicate QuEChERS extractions, performed on soil spiked with deuterated internal standards at $50 \mathrm{ng} / \mathrm{g}$ added prior to extraction, were used to assess the compound recovery (details of sample preparation given in a recent application note (AN10720). Triphenyl phosphate at $100 \mathrm{ng} / \mathrm{g}$ was added post extraction and used as internal standard to adjust for potential injection variability (Appendix 5 - Table 5). All compounds show good recoveries with the average values of $79 \%$ (Appendix 5 - Table 5). Lower boiling point compounds, such as naphthalene- $d_{8}$, had lower recoveries that could be explained by losses during the solvent evaporation phase.
Although the recovery of such compounds is low, precision of measurement over $n=7$ replicate extractions was
$<15 \%$ RSD for all compounds and the majority being $<5 \%$. This clearly demonstrates that the QuEChERS extraction and dSPE procedure method is highly reproducible and therefore suitable for analytical testing laboratories. The total sample preparation time was $<2$ hours, which compared to typical Soxhlet extractions of 24-48 hours, and is a significant time (and cost) savings of 10-20x.

## Quantification of PAHs and PCBs in QuEChERS soil extracts

Soil samples, extracted as described in AN10720, were analyzed for their native incurred residues. The quantitative performance of the method in terms of sensitivity and selectivity is highlighted below with examples of low level native incurred residues (Figure 5).

Figure 5. Examples of FS XIC chromatograms (quantification in black, and confirmation ions in blue) for phenanthrene in soil (top left), anthracene in soil (top right), PCB-28 in soil (bottom left), and 9-fluroenone in soil (bottom right). Below each of the FS XIC chromatograms the following is annotated: (i) amount found in sample as $\mu \mathrm{g} / \mathrm{kg}$, (ii) ion ratio deviation from the calibration average, (iii) measured mass ( $\mathrm{m} / \mathrm{z}$ ), (iv) theoretical mass ( $\mathrm{m} / \mathrm{z}$ ), (v) chemical formula, and (vi) mass error (ppm).

In summary, the results obtained in these experiments demonstrate that a consolidated compound class method using a modified QuEChERS sample preparation can be used to quantify PAHs and PCBs in soils. In the case of PCB-28, low levels of incurred residues of $0.6 \mu \mathrm{~g} / \mathrm{kg}$ were detected and quantified within an ion ratio deviation from the calibration of only $0.7 \%$ and a mass error of the theoretical exact mass of 0.2 ppm with minimal matrix interferences all while in FS.

## Screening for additional soil contaminants

The advantages of acquiring data in FS with high resolution and accurate mass were leveraged through retrospective analysis of samples and additional screening of unknown contaminants with confirmation by chemical ionization (CI). The Compound Discoverer platform includes a streamlined workflow for GC EI data allowing for extraction, deconvolution, and putative identification of the unknowns based on mass spectral library matching (NIST 2017). The software first performed spectral deconvolution above a customizable signal to noise ( $\mathrm{S} / \mathrm{N}$ ) followed by compounds detection and grouping to consider compounds that
elute at the same retention time (within $\pm 6 \mathrm{~s}$ window). The deconvoluted spectra were then searched against mass spectral libraries (such as NIST), and the hits were scored based on the total score derived from a combination of library search index (SI) score and presence/absence of the molecular ions as well as percentage of fragment ions that can be explained from the NIST elemental composition. The use of a retention index acquired under the same conditions used for sample analysis helped to increase the confidence in compound identification. Compounds detected with NIST SI scores >750 can be seen in (Figure 6A). With the Compound Discoverer browser an overlaid XIC of the peak eluting at $10.95 \mathrm{~min}(\mathrm{~m} / \mathrm{z} 136.07579)$ was identified as the top hit versus NIST library (Figure 6B). The peak was putatively identified as pyriproxyfen with a SI score of 953; however, the molecular ion of $m / z 321.135945$ was not observed, which demonstrates the requirement for additional chemical ionization and mass accuracy confirmation of molecular ions. Full results of the EI NIST matches for the deconvoluted data can be found in the (Appendix 6 - Table 6).

Figure 6. (A) Example NIST SI match scores for compounds detected in the deconvoluted El spectra QuEChERS soil extract spiked at $100 \mathrm{pg} / \mu \mathrm{L}$. (B) Compound Discoverer software El spectrum of a spiked QuEChERS soil extract - deconvoluted versus NIST library of the peak eluting at 10.95 min ( $\mathrm{m} / \mathrm{z} 136.07579$ ), with the structure of the top SI match pyriproxyfen from the result table.

Full-scan data for blank and spiked QuEChERS soil extracts ( $100 \mathrm{pg} / \mu \mathrm{L}$ ) were analyzed with Compound Discoverer 3.2 software for putative identification of peaks. A complete workflow was used to identify compounds with a high degree of confidence using deconvoluted El spectra based on search index scores (SI) and confirmation of the corresponding molecular ion and or adducts using positive chemical ionization. FS data was acquired using Chromeleon 7.3 in El and PCI modes at 60,000 FWHM resolution and then imported in Compound Discoverer 3.2 software. The software was used to deconvolute, align, and filter the peaks to putatively identify the compounds using mass spectral library match (NIST 17). The power of the deconvolution algorithms become clear when overlaying both the FS TIC and deconvoluted spectra for analytes eluting in a crowded area of the chromatogram (Figure 7).

Confirmation of suspect contaminants using positive chemical ionization
Further confirmation used in the identification of compounds was achieved by assessing the PCl spectra to identify the elemental composition of the parent ion by looking at common adducts. In PCI experiments using methane as the reagent gas, three adducts are typically observed: $[\mathrm{M}+\mathrm{H}]^{+}$, $\left[\mathrm{M}+\mathrm{C}_{2} \mathrm{H}_{5}\right]^{+}$, and $\left[\mathrm{M}+\mathrm{C}_{3} \mathrm{H}_{5}\right]^{+}$. An example was shown for a peak at 9.44 min, which was identified as flutolanil versus the NIST library; however, the molecular ion $m / z 323.11276$ was not giving a significant response (Figure 8 A ). When looking at the PCl data for this compound a significant boost in the molecular ion was observed with minimal mass error of $0.09 \mathrm{ppm}\left(\right.$ Figure 13B). Two additional adducts $[\mathrm{M}+\mathrm{H}]^{+}$ and $\left[\mathrm{M}+\mathrm{C}_{2} \mathrm{H}_{5}\right]^{+}$were also observed with ppm mass errors of -0.1 and -0.03 ppm respectively. Full results of the PCl confirmation can be found in Appendix 7 - Table 7.

Figure 7. (A) Overlaid FS $(m / z=50-550)$ TIC for a soil QuEChERS extract spiked with pesticides at $100 \mathrm{pg} / \mu \mathrm{L}$. (B) Compound Discoverer 3.2 software deconvoluted El spectrum showing closely eluting compounds extracted from the complex TIC FS data.

Figure 8. (A) Compound Discoverer software El spectrum of a spiked QuEChERS soil extract - deconvoluted versus NIST library of the peak eluting at $9.437 \mathrm{~min}(m / z 323.11243)$, with the structure from the top SI match flutolanil from the result table. (B) PCI mass spectrum for flutolanil displaying adducts $[\mathrm{M}+\mathrm{H}]^{+}$and $\left[\mathrm{M}+\mathrm{C}_{2} \mathrm{H}_{5}\right]^{+}$used for confirmation of this compound in conjunction with the El data.

## Conclusions

The results of the experiments presented demonstrate that modified QuEChERS methods and the TriPlus RSH autosampler in combination with the Orbitrap Exploris GC provides an ideal solution for analytical testing laboratories looking to improve productivity and deliver confident results.

- Comprehensive method consolidation with chromatographic separation and overall analytical performance was achieved for the analysis of PAHs and PCBs in soil in <20 min.
- Increased throughput of up to 20x can be realized by using a modified QuEChERS method compared to tradition Sohxlet extraction methods, saving cost and time.
- Femtogram level sensitivity was achieved using the Orbitrap Exploris GC, with the MDLs values calculated for 45 native compounds ranging from 115 to 475 fg OC (corresponding to $0.1-0.5 \mu \mathrm{~g} / \mathrm{kg}$ in sample).
- LOQs ranged from 0.5 to $5.0 \mu \mathrm{~g} / \mathrm{kg}$ in soil as determined from $n=18$ repeat injections of the lowest serially diluted matrix-matched standard that satisfied the acceptance criteria defined below:
- Ion ratios within $\pm 30 \%$ of the expected values calculated as an average across a calibration curve ranging from 0.1 to $500 \mathrm{pg} / \mu \mathrm{L}$ (equivalent to $0.4-5.0 \mu \mathrm{~g} / \mathrm{kg}$ in sample)
- Peak area repeatability of <15\% RSD
- Linearity was achieved across a calibration range of $0.1-500 \mathrm{pg} / \mu \mathrm{L}$ (corresponding to $0.1-500 \mu \mathrm{~g} / \mathrm{kg}$ in soil) showed coefficient of determination values of $R^{2} \geq 0.995$, and residuals <13\%.
- All compounds show good recovery overall with the average internal standard recovery being 79\%, and precision of the seven technical replicate extractions $<5 \%$ RSD.
- Quantitative performance with soil samples was excellent as demonstrated by the closeness of the ion ratios and mass error compared to expected values when used for confirmation of low-level incurred residues in soil such as PAHs, PCBs, and oxyPAHs.
- Rapid change-over from El (for spectral library search) to softer ionization such as PCI (for molecular ion confirmation using adduct information) is possible.
- The streamlined GC-El data processing workflow with Compound Discoverer software allows for quick extraction, deconvolution, and identification of unknown compounds.

Appendix 2 - Table 2. Details of the 14 internal standards, including compound type, CAS number, and concentration (suffix "L" indicates mass-labeled)

| Internal standard | Compound type | CAS Number |
| :--- | :---: | :---: | :---: |
| Napthalene-d-8 | PAH | $1146-65-2$ |
| Dibenzofuran-d8 | PAOH | $93952-04-6$ |
| 9-Fluorenone-d8 | oxyPAH | $137219-34-2$ |
| Pyrene-d-10 | PAH | $1718-52-1$ |
| PCB-28L | PCB | $7012-37-5$ |
| PCB-52L | PCB | $35693-99-3$ |
| PCB-101L | PCB | $37680-73-2$ |
| PCB-118L | PCB | $31508-00-6$ |
| PCB-153L | PCB | $35065-27-1$ |
| PCB-138L | PCB | $35065-28-2$ |
| PCB-180L | PCB | $35065-29-3$ |
| Quinoline-d7 | PANH | $34071-94-8$ |
| o-Terphenyl | aromatic | $84-15-1$ |
| Perylene-d-12 | PAH | $1520-96-3$ |

Appendix 3 - Table 3. Method LOQs were determined from the lowest serially diluted spiked QuEChERS extract solution prepared as detailed in the experimental section, which pass the criteria. Eighteen replicate injections of each of the diluted standards ranging between $0.5 \mathrm{pg} / \mu \mathrm{L}$ and $5.0 \mathrm{pg} / \mu \mathrm{L}$ were performed. The criteria used to assess individual LOQs were (i) measured ion ratio (IR) $\pm 30 \%$ compared to the target ion ratio calculated from the average ion ratio across the calibration range and (ii) peak area $<15 \%$ RSD.

| Compound | Injected amount (pg OC) | Min IR \% dev | Max IR <br> \% dev | $\begin{aligned} & \text { Mean IR \% } \\ & \text { dev } \end{aligned}$ | Peak area \% RSD | $\begin{gathered} \text { LOQ } \\ (\mathrm{pg} \mathrm{OC}) \end{gathered}$ | $\begin{gathered} \text { LOQ } \\ (\mu \mathrm{g} / \mathrm{kg}) \end{gathered}$ |
